Where innovation starts

Context

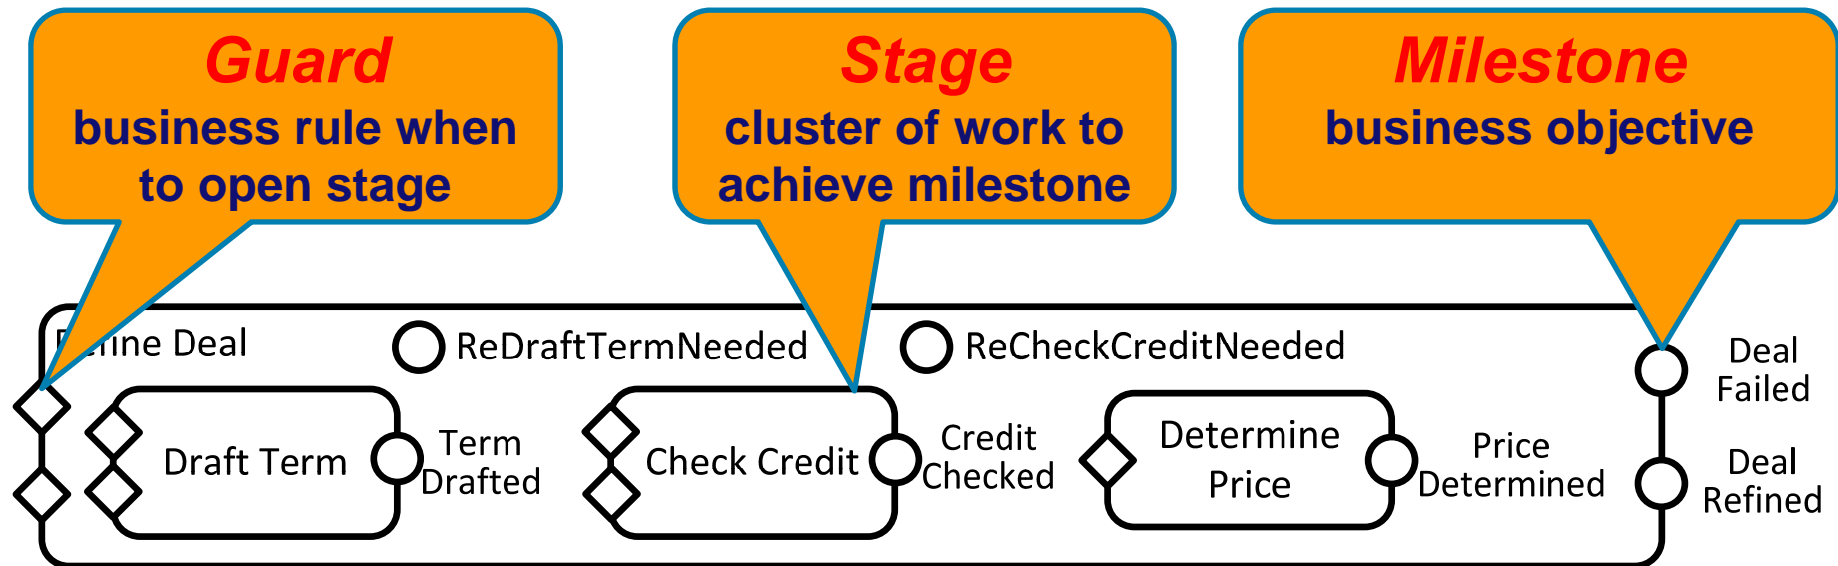

Motivation

- **Business Process Outsourcing (BPO): part of a business process is performed by another organization**
- **Cloud-computing is key enabler of BPO**

This study

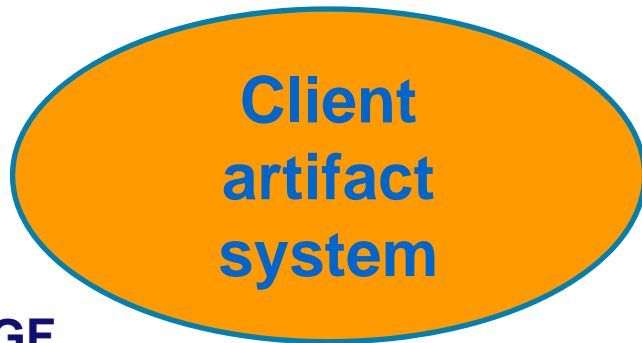

- **BPO for declarative case management**
 - **Spez., Guard-Stage-Milestone business artifact model**
 - **GSM is basis for OMG's CMMN standard**
- **Main result: framework that**
 - **enables BPO at design-time and run-time**
 - **supports hiding business logic**

Guard-Stage-Milestone (GSM) schemas

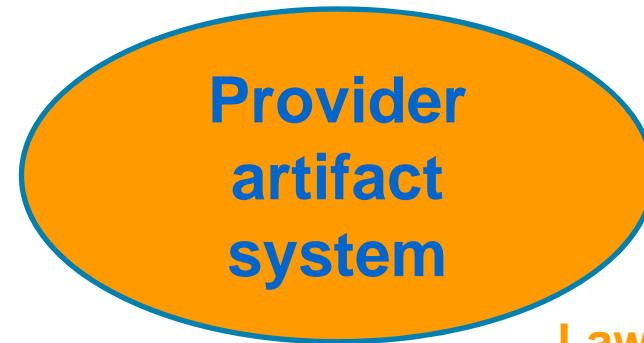

- **Status of each stage, milestone $\in \{ \text{on}, \text{off} \}$**
- **Business rules specify when stage/milestone changes state**
 - Might refer to status of other stages/milestones
- **Rules need to be evaluated in right order to ensure that all changes have maximal effect**
- **Unit of change triggered by external event is called a B-step**

Problem: outsourcing GSM subschema

IGF

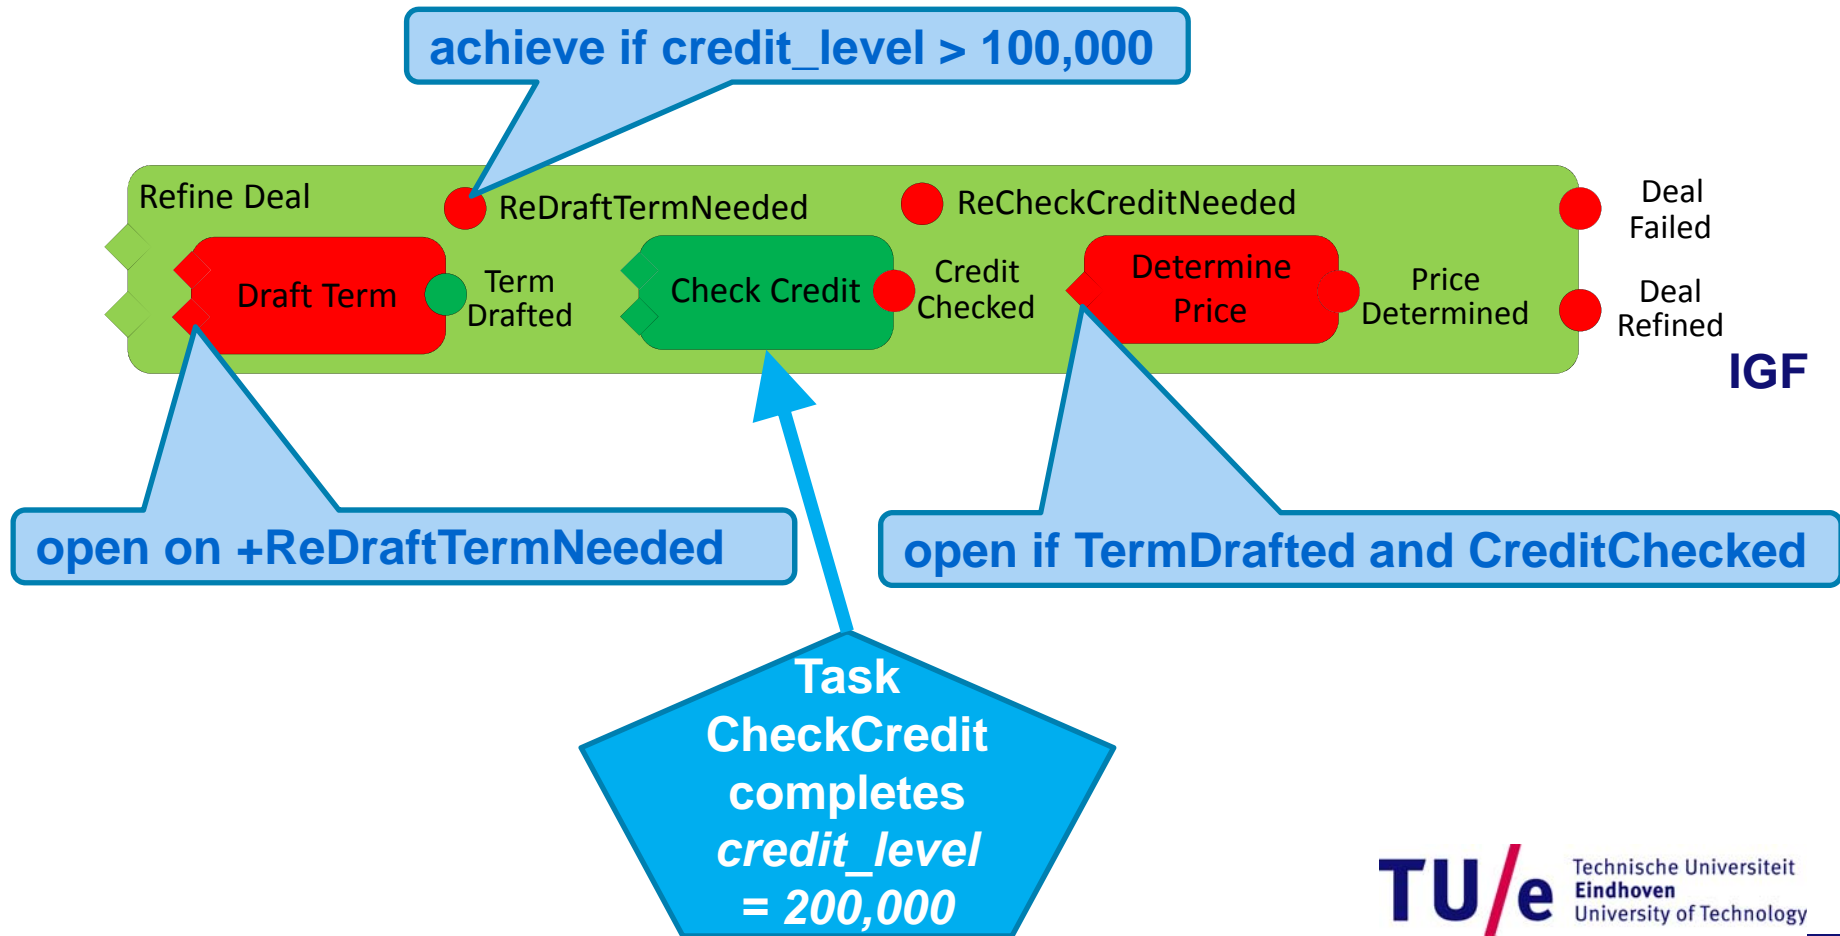

LawOffice

must be equivalent

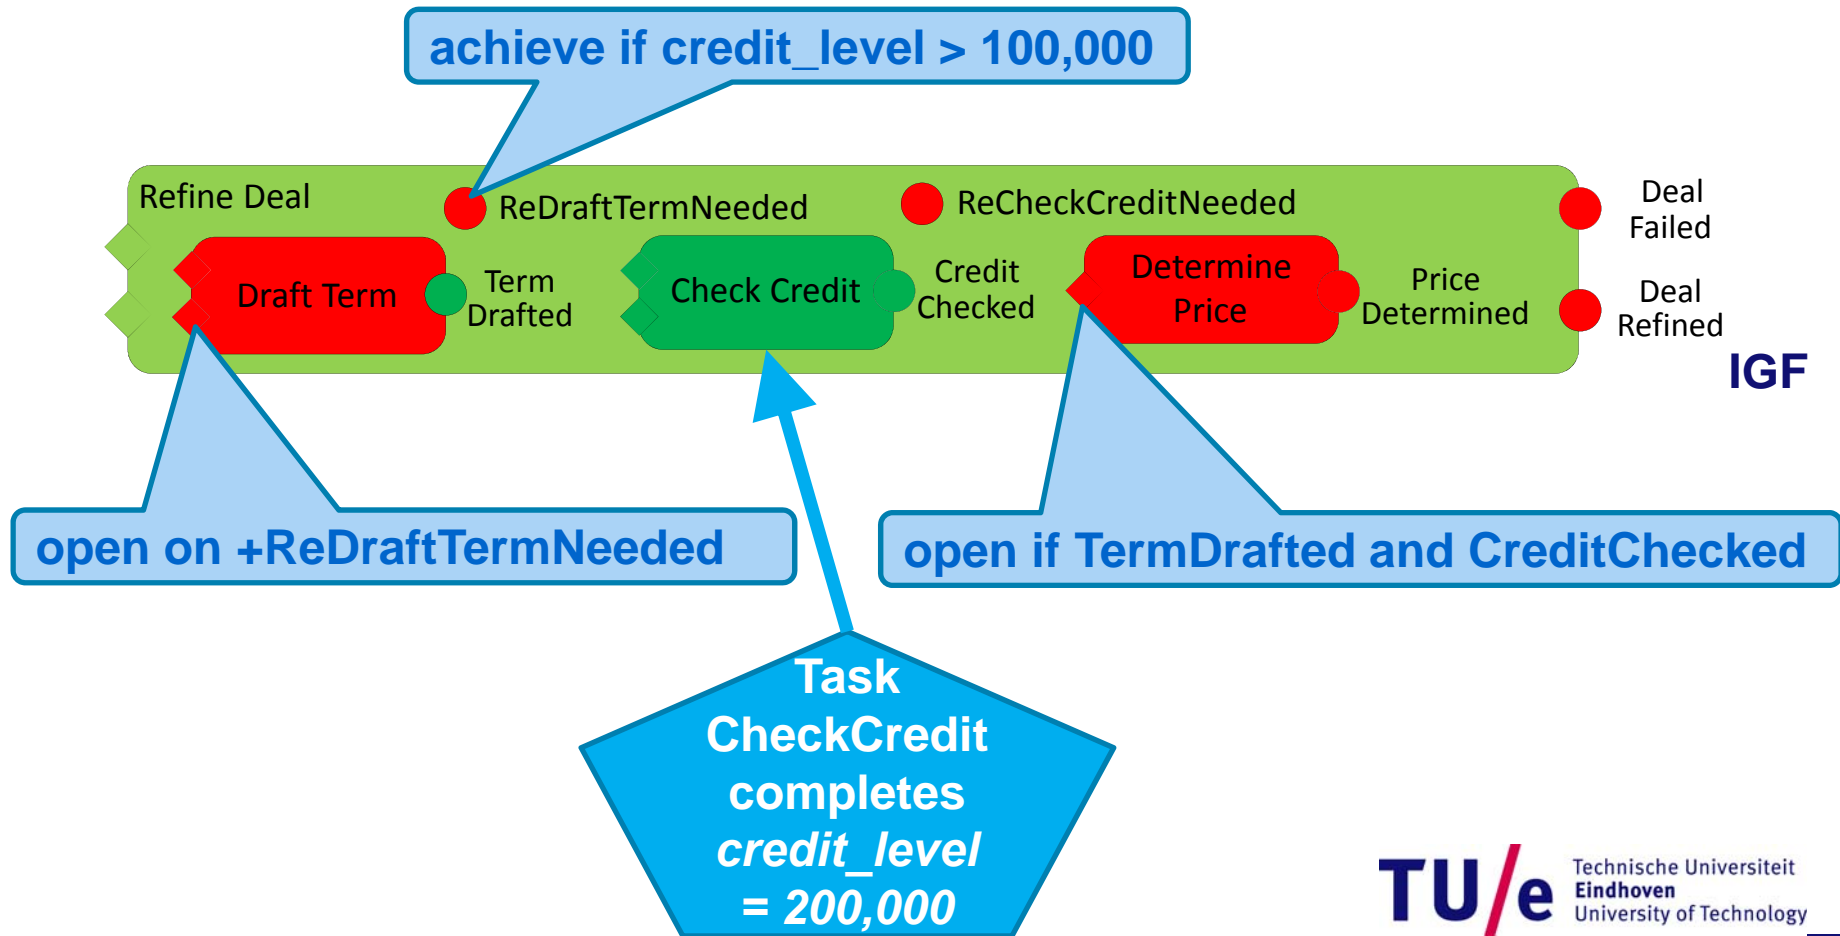

Example scenario in original GSM schema

- status is on
- status is off

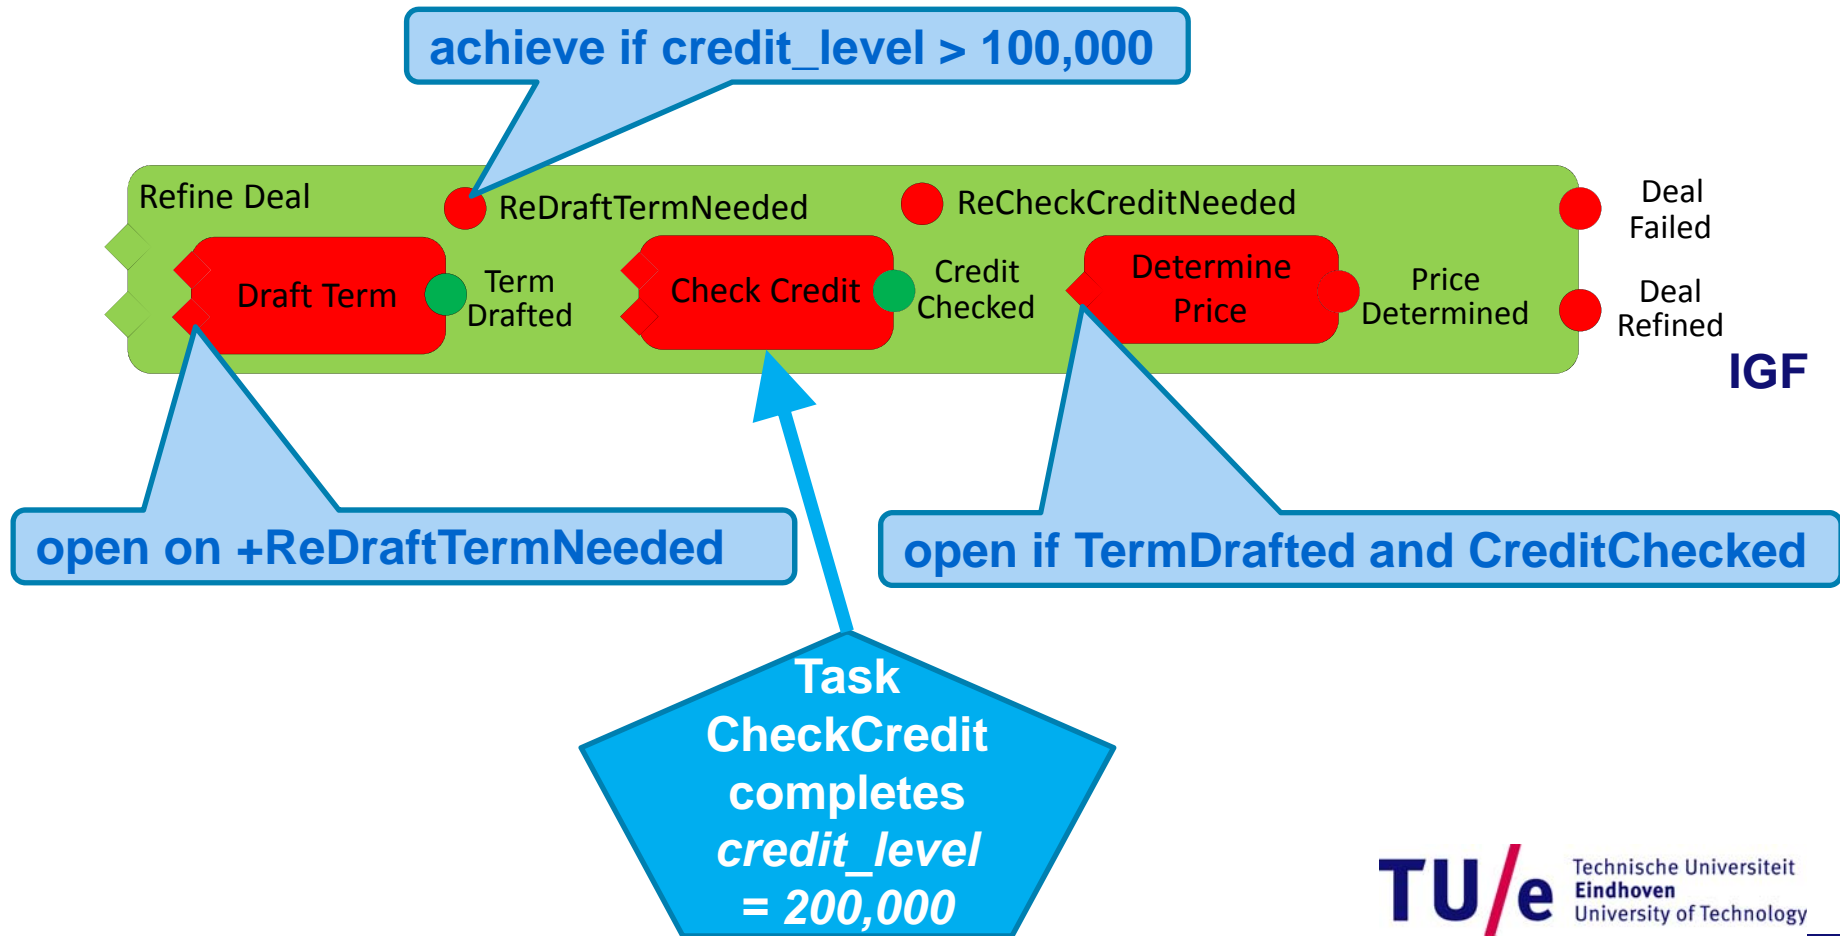

Starting B-step (1)

- status is on
- status is off

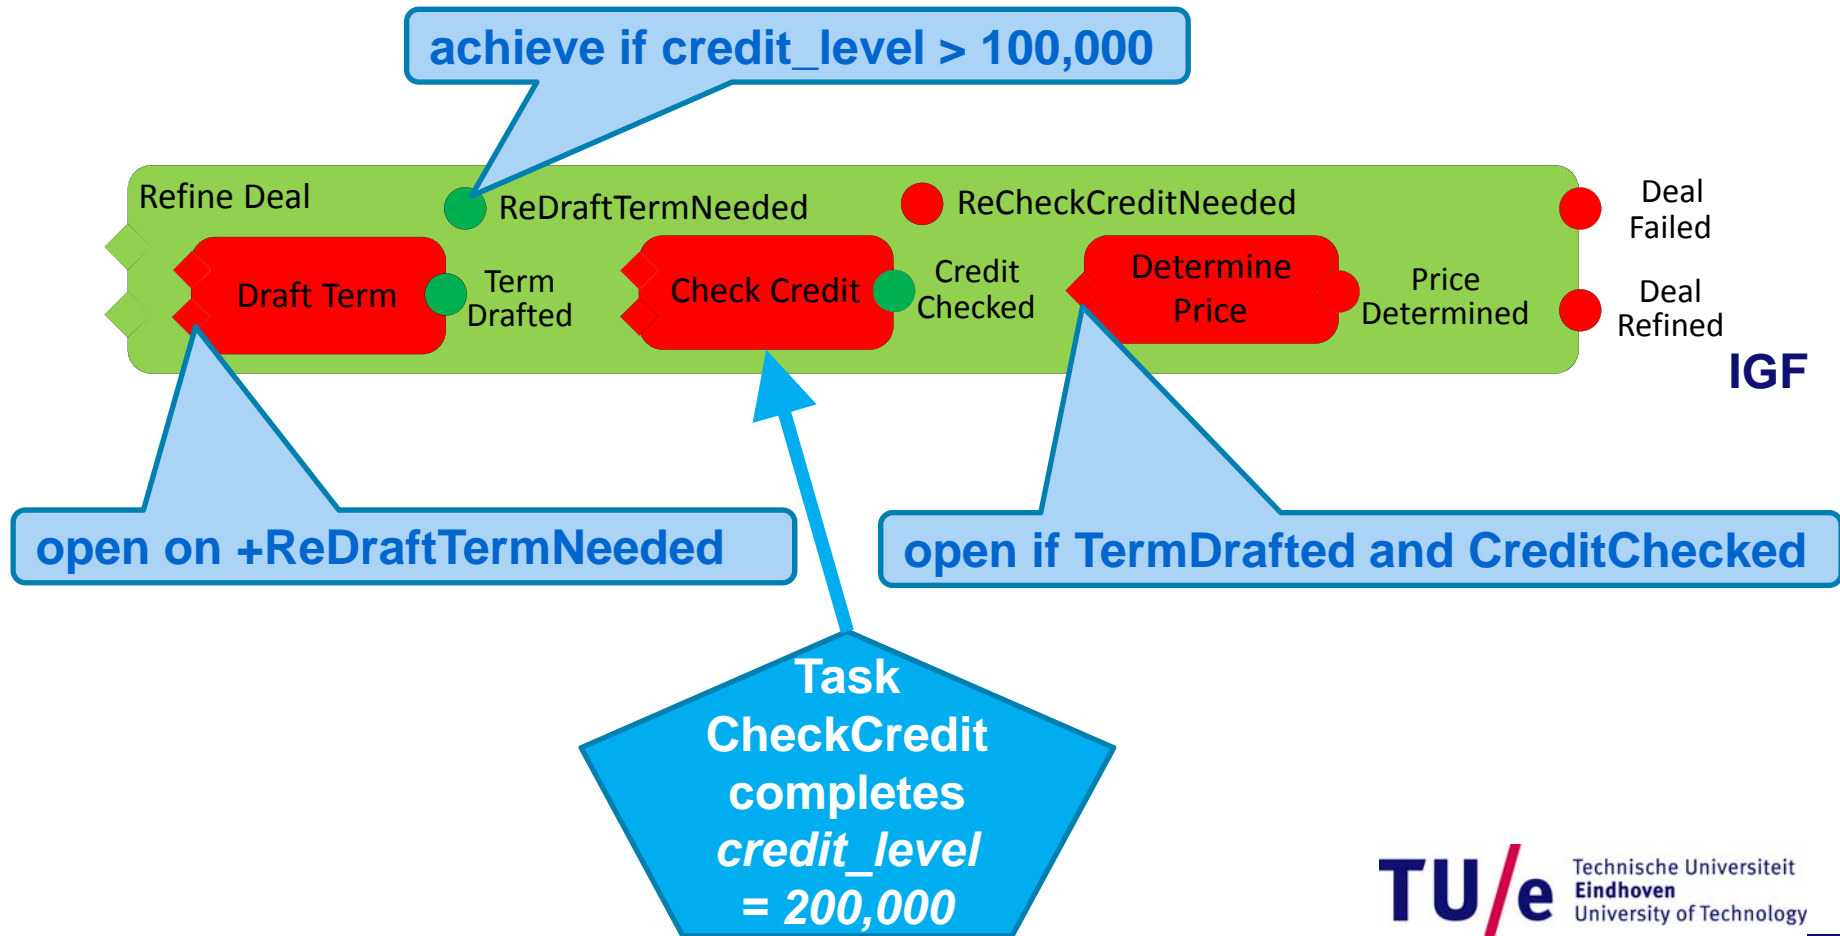

Continuing B-step (2)

- status is on
- status is off

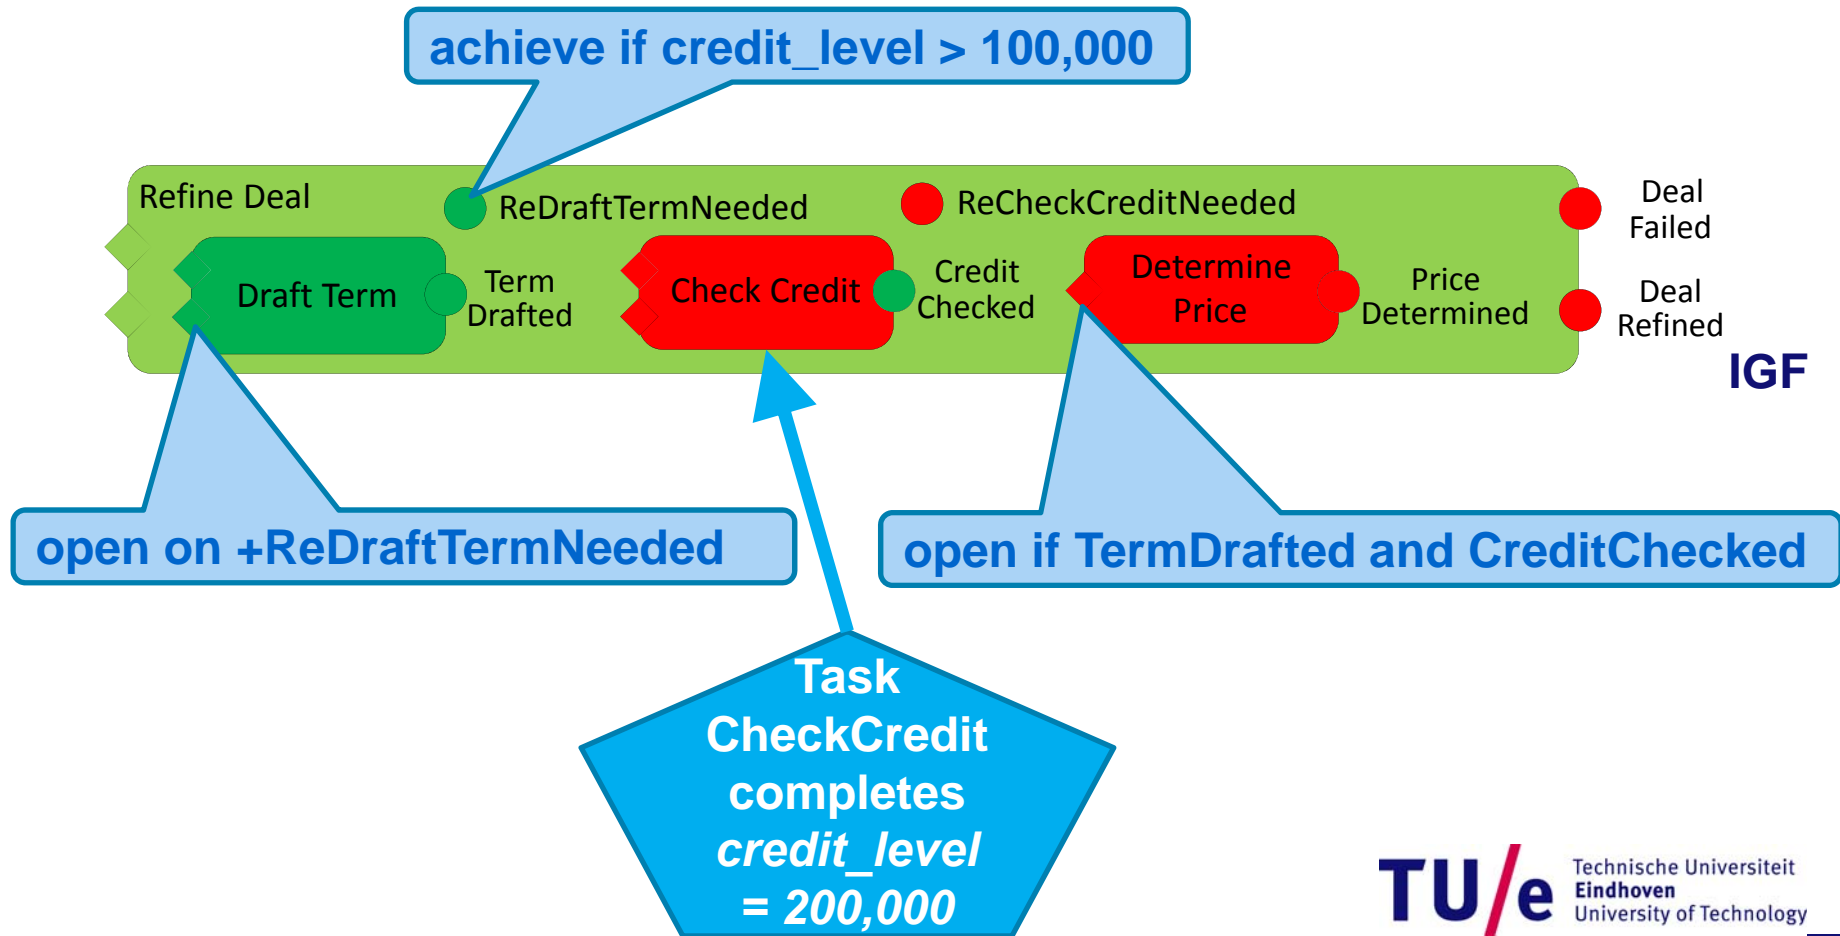

Continuing B-step (3)

- status is on
- status is off

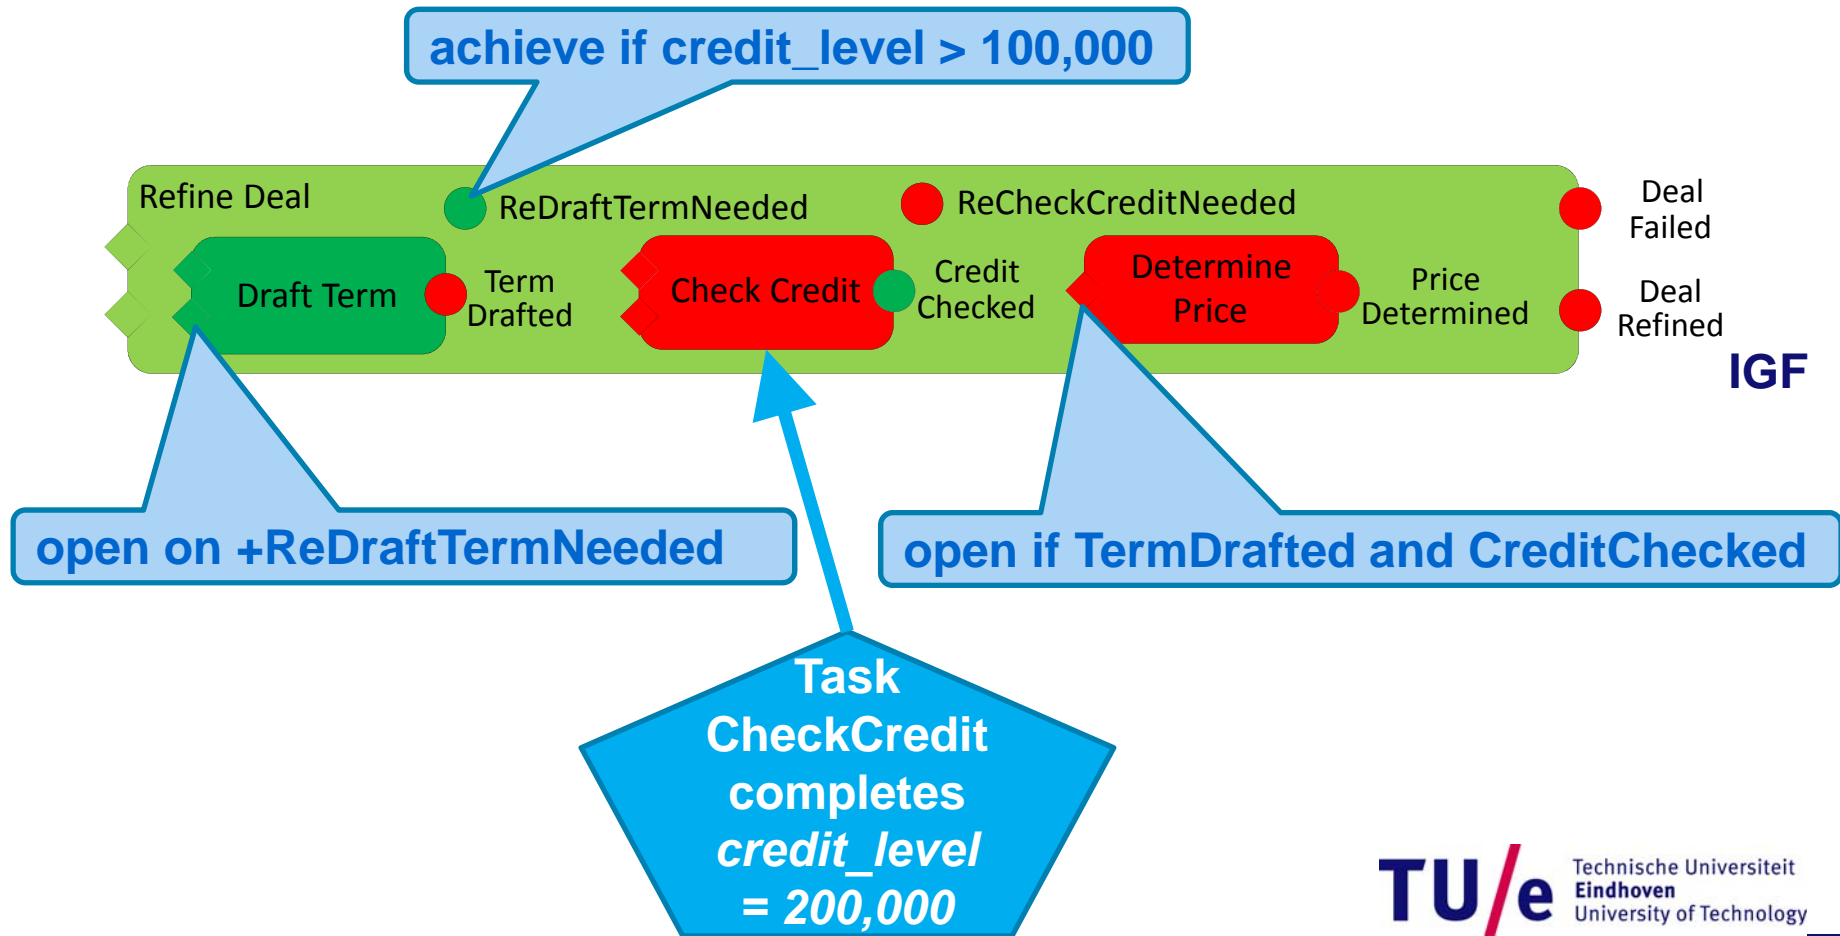

Continuing B-step (4)

- status is on
- status is off

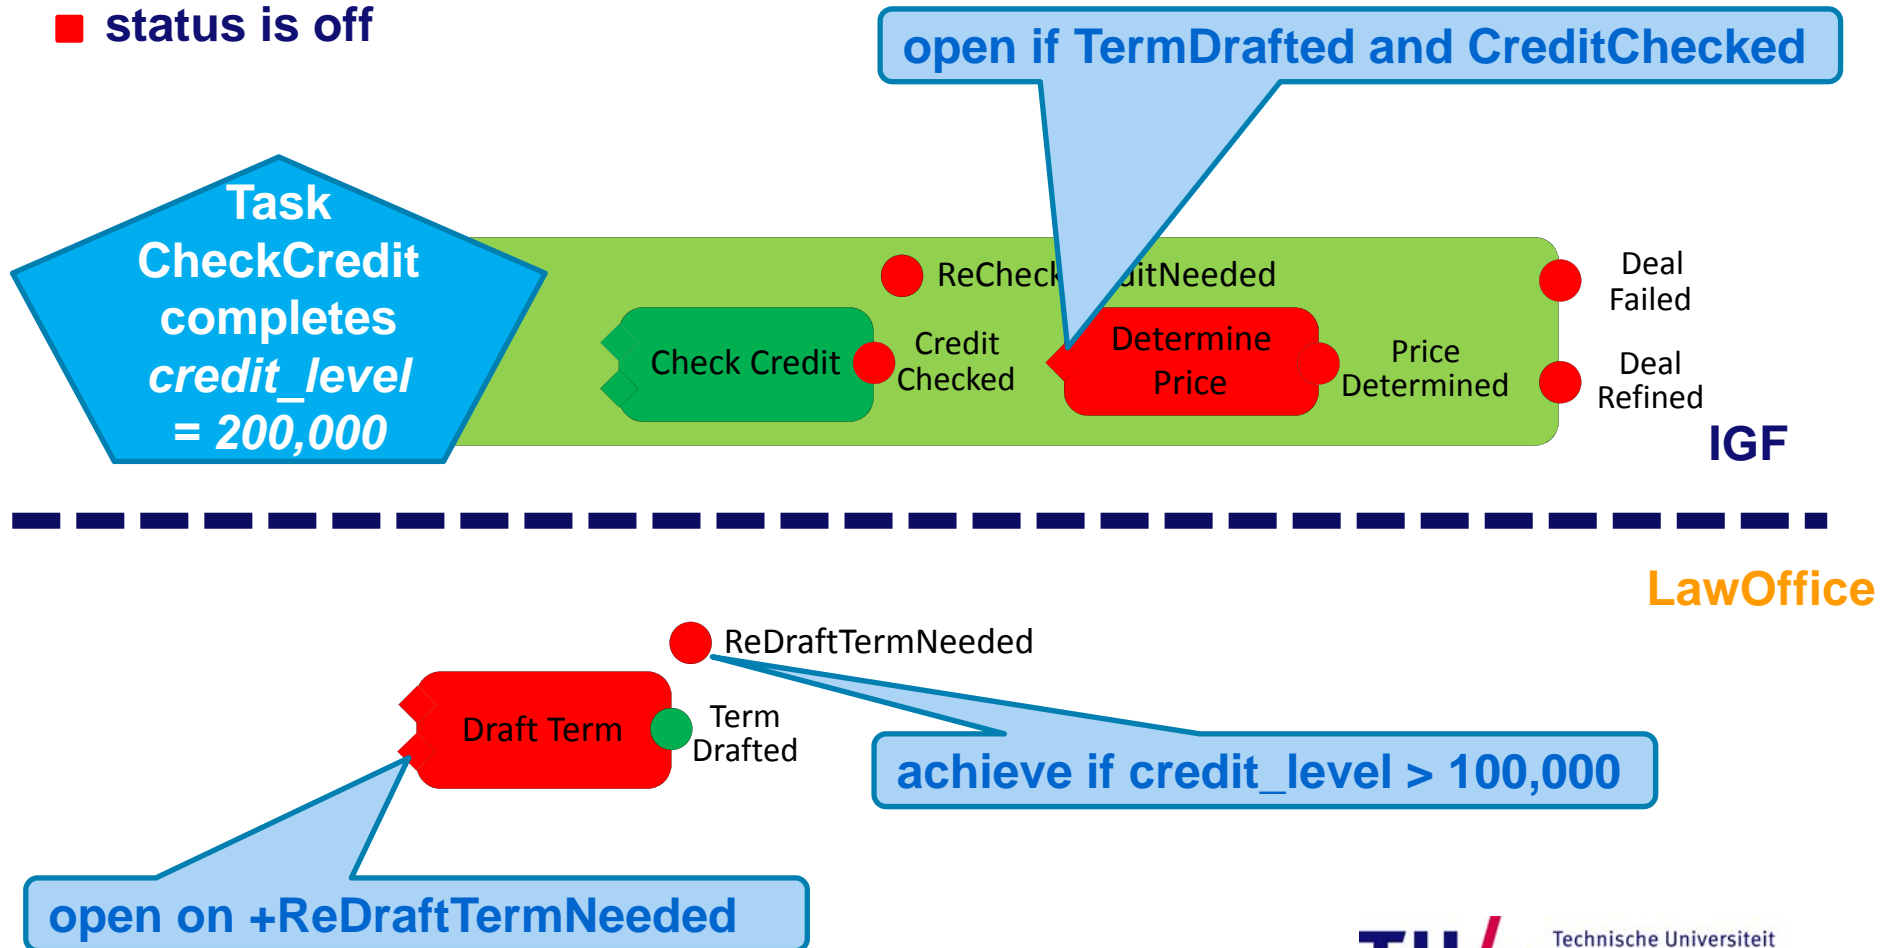

End of B-step (5)

- status is on
- status is off

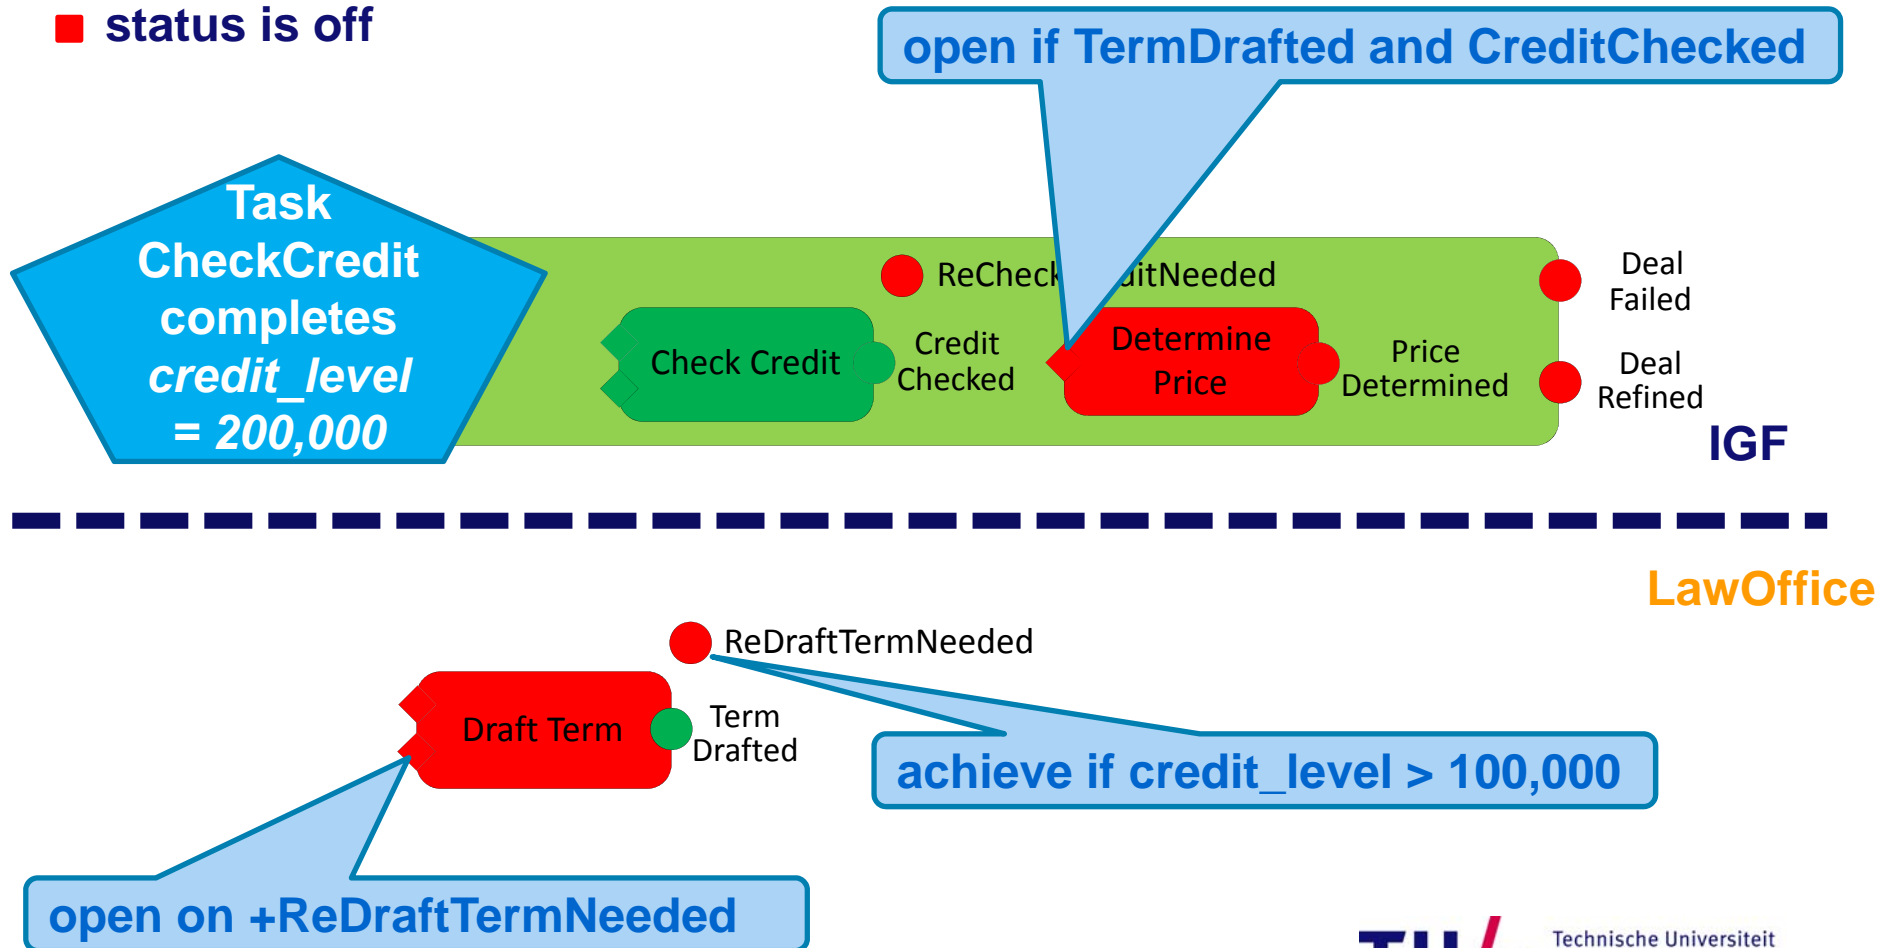

Splitting example scenario results in race condition

- status is on
- status is off

- status is off

LawOffice

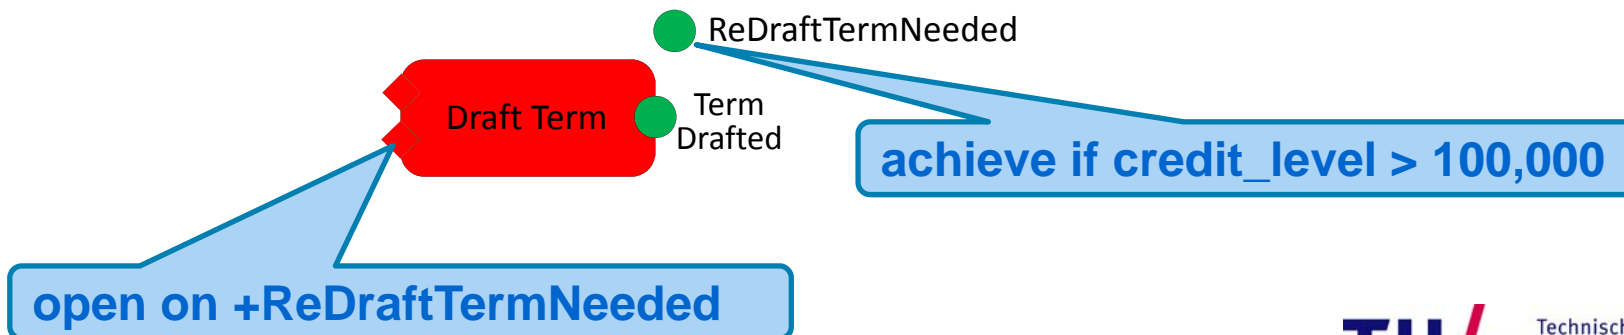

Splitting example scenario results in race condition

- status is on
- status is off

Possible solutions

1. Extend local GSM engines with complex synchronization logic
2. Better: restructure GSM schema to avoid complex synchronization

Solution approach

- Keep **local cache** of status of needed remote stages/milestone
 - determined per external event type
- **Reallocate business rules** to avoid complex synchronization
 - Sometimes: rule executes at different location than the corresponding stage/milestone
- Runtime simulation protocol based on distributed 2-phase commit
- Result (see paper): split GSM schema faithfully simulates original GSM schema

Formal results

Theorem 1

- Let Σ be a snapshot of GSM schema Γ ;
- Let schemas Γ_1 and Γ_2 be a “split” of schema Γ ;
- Let snapshots Σ_1 and Σ_2 be the split of Σ ;
- Let e be an external event of type E ;
- Then: the application of e on (Σ_1, Σ_2) faithfully simulates the application of e on Σ

Theorem 2

- Using the “runtime simulation protocol” (see paper) the above result generalizes to streams of external events.

Yet another problem...
... revealing of secrets

Alternative outsourcing scenario

- status is on
- status is off

Result on privacy

- Let Γ be GSM schema and let H be a set of attributes whose rules should be hidden.
- Construct $\Gamma' = \text{hide}(\Gamma, H)$ as follows
 - For hiding the rules of n status attributes, in centralized GSM model
 - For each hidden status attribute a , create an anonymous event E_a
 - Each rule that triggers a is transformed into a rule that triggers a stage that generates E_a
- Lemma: each B-step of Γ is faithfully simulated by a cluster of $n + 1$ B-steps of Γ' .
- To perform splitting with hidden status attributes, create $\Gamma' = \text{hide}(\Gamma, H)$ and split Γ' .

Complete algorithm

- **Input:**
 - GSM schema Γ
 - desired split of stages/milestones
 - status attributes H whose rules are to be hidden
- **Step 1: introduce anonymous events in $\Gamma \rightarrow \Gamma'$**
- **Step 2: perform splitting on $\Gamma' \rightarrow (\Gamma_1, \Gamma_2)$**

- **Main result (see paper):**
 - (Γ_1, Γ_2) faithfully simulates Γ
 - (Γ_1, Γ_2) does hide rules for status attributes in H

Conclusion

- **Comprehensive framework for supporting outsourcing of GSM schemas**
- **Covers both design-time and run-time**
- **Future work:**
 - **multi-party outsourcing**
 - **interacting artifact types**
 - **extend results to OMG's Case Management Modeling Notation**

Thank you!
